# Limitations of Direct Kinematics

Good measurement of mass distribution

J.P. Unik, IAEA –SM-174/209

Incomplete  
Measurements of  
Isotopic distributions

limitations for heavy ff  
- lifetimes  
- unknown level schemes

Isotopic distribution by  
 $\gamma$ -spectroscopy

A. Bail PRC 84(2011)

# Goals of Inverse kinematics

Kinematical boost increases the kinetic energy of the fission fragments providing **the capability of a direct identification**

Kinematical boost allows to keep a wide angular coverage in the CM frame when the size of the detectors is limited

# Reaction Mechanism

Fissioning Systems

Fissioning systems not accessible from any other mechanism

10% above Coulomb barrier

**Transfer-Fission:**

10 n-rich actinides produced with a distribution of  $E_x$  below 30 MeV

**Fusion-Fission:**

production of  $^{250}\text{Cf}$  with  $E_x = 46 \text{ MeV}$   
10 times more likely than any transfer channel

# Transfer Reaction and Excitation Energy

Distribution of  $E_x$  for the  
different fissioning systems from  
reconstruction of the binary  
reaction

Higher  $E_x$  for higher number of  
transferred nucleons

$E_x \sim 8$  MeV is comparable with  
fast-neutron fission

C. Rodriguez-Tajes et al.,  
PRC (2014) 024614

# Excitation of Target-like Recoil

EXOGAM detector allow us to evaluate the excitation probability of the target-like nuclei

$\gamma$ -rays measurements show excited states in  $^{12}\text{C}$ ,  $^{11}\text{B}$  and  $^{10}\text{Be}$  in coincidence with fission with  $P_\gamma = 0.12\text{-}0.14$

# Fission Fragments Detection

M. Rejmund et al., NIM A 646 (2011) 184  
 S. Pullanhiotan et al., NIM A 593 (2008) 343

# Fission Fragments Identification

Mass Identification

Proton Number Identification

$A/Q$  provides the  $Q$  separation and contributes to a better  $A$  resolution

More than 300 isotopes identified

$\gamma$ -rays in coincidence with fission fragments provide a cross check for the  $Z$  and  $A$  identification

A. Shrivastava et al. PRC 80 (2009) 051305

# Transmission through VAMOS

The detection is limited by the transmission

The transmission is different for different isotopes

Beam normalization for different settings is required as well

We need to recover all the charge states per isotope and compensate the acceptance in the azimuthal and polar angles

$$Y(Z, A) = I(Z, A) \frac{2}{Range(Z, A)}$$

# Isotopic Fission-Fragment Distribution

$^{238}\text{U}$

$^{239}\text{Np}$

$^{240}\text{Pu}$

$^{244}\text{Cm}$

$^{250}\text{Cf}$

# Fission Yields

Mass-yields and Z-yields distribution of 5 different fissioning systems, most of them exotic nuclei

New complete measurements, difficult to produce by n-capture

Measurements of fragment distributions of  $^{239}\text{Np}$  is scarce ( $T_{1/2} (^{238}\text{Np}) = 2.1$  d)

There is no direct measurements of fragment distributions of  $^{244}\text{Cm}$

The contribution of the symmetric mode disappears for the systems at low excitation energy

The shift in  $Z$  of the light fragments reflects the atomic number of the fissioning system

# Neutron Excess

Evolution of the polarization with the  $E_x$  and the fissioning system

Clear accumulation of  $N$  driven by the double magic nucleus  $^{132}\text{Sn}$

Charge Polarization present in all the systems

# Neutron Excess

$^{240}\text{Pu}$

$^{238}\text{U}(^{12}\text{C}, ^{10}\text{Be}) ^{240}\text{Pu}$

Different positions of gate  
along the  $E_x$  distribution

The  $\langle N \rangle / Z$  ratio gets reduced around  $Z \approx 50$  by increasing  $E_x$ , signature of a closed shell which effect is smaller for higher  $E_x$ .

$^{240}\text{Pu}$

# Average Velocity

PRELIMINARY

In the asymmetric region, the light fragment is emitted with a higher velocity compared with the LDM

$$\langle V_{fiss} \rangle = \frac{\sum_A V_{fiss}(Z, A) \cdot Y(Z, A)}{\sum_A Y(Z, A)}$$

Velocity decrease with higher  $E_x$   
The distance between both fragments at the scission point is larger with higher  $E_x$

$^{240}\text{Pu}$

# Average Total Kinetic Energy

PRELIMINARY

$$TKE = u \cdot \langle A \rangle_Z \cdot (\langle \gamma \rangle_Z - 1) + u \cdot \langle A \rangle_{Z_{Act}-Z} \cdot (\langle \gamma \rangle_{Z_{Act}-Z} - 1)$$

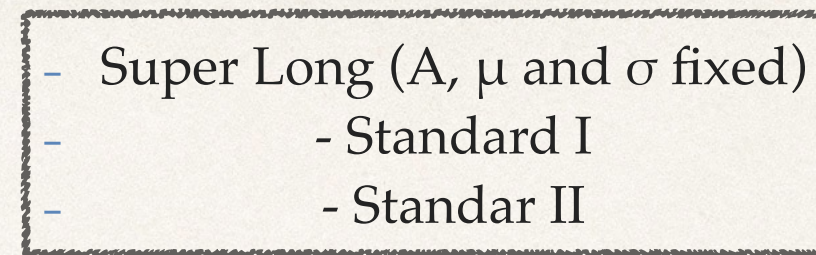

TKE values decrease with higher  $E_x$

- Larger distance at scission point
- Larger neutron evaporation

# Excitation Energy Dependence

Both Standard positions appear above the K.-H. Schmidt prescription

K.-H. Schmidt et al., Nucl. Phys. A 665, 221 (2000)

We observe an evolution of the position and the integrals of the asymmetric modes Standard I and Standard II

# Excitation Energy Dependence

The evolution of the fission channels becomes more clear in this case

# Excitation Energy Dependence

Fissioning system with higher statistics  
Both positions increase with the  $E_x$  for SI and SII. The evolution of the integrals is also clear

The SuperLong channel becomes more important for higher excitation energy

$^{244}\text{Cm}$

# Excitation Energy Dependence

$^{250}\text{Cf}$

The Standard III is needed to explain the shape of the distribution of  $^{244}\text{Cm}$  and  $^{250}\text{Cf}$

SuperLong Channel becomes relevant for these ranges of  $E_x$

SI :  $\bar{Z} = 52.9$   $I = 5.22$   
SII :  $\bar{Z} = 56.1$   $I = 27.13$   
SIII :  $\bar{Z} = 59.7$   $I = 16.80$

$^{244}\text{Cm}$

# Conclusions

Transfer-induced fission in inverse kinematics coupled to the VAMOS spectrometer allowed:

- The study the fission of different fissioning systems (  $^{238}\text{U}$ ,  $^{239}\text{Np}$ ,  $^{240}\text{Pu}$ ,  $^{244}\text{Cm}$  and  $^{250}\text{Cf}$ ).
- The excitation energy measurement distribution through the transfer reaction kinematics.
- The full isotopic identification of fission fragments using the VAMOS spectrometer.

The effect of shell structure was observed as a function of the excitation energy.

- The evolution of the fission fragments from asymmetric to symmetric distributions.
- The  $\langle N \rangle / Z$  ratio at  $Z \approx 50$  decreases by increasing the excitation energy.
- The TKE decreases by increasing the excitation energy.

Fission Fragment Distribution were investigated in terms of Fission Channels Interpretation

- The SI, SII and SIII are needed to reproduce the almost gaussian shape of  $^{250}\text{Cf}$
- Observed an evolution of the position and the integral of SI and SII with the excitation energy depending on the fissioning system

# Fission Barriers

We observe a general agreement with previous data with small discrepancies

First and second chance are measured in  $^{240}\text{Pu}$  and  $^{241}\text{Pu}$
